Sliding Window Search

Sliding Window Search

Another way to approach the sliding window method is to apply a convolution, which will maximize the number of "hot" pixels in each window. A convolution is the summation of the product of two separate signals, in our case the window template and the vertical slice of the pixel image.

You slide your window template across the image from left to right and any overlapping values are summed together, creating the convolved signal. The peak of the convolved signal is where there was the highest overlap of pixels and the most likely position for the lane marker.

Now let's try using convolutions to find the best window center positions in a thresholded road image. The code below allows you to experiment with using convolutions for a sliding window search function. Go ahead and give it a try.
